British Airways Customer Review Analysis — Kaustubh Sahu, Data Analytics Intern, Labmentix

Target delivery time: 7-8 minutes

[Slide 1 — Title]

Good morning/afternoon everyone, and thank you for the opportunity to present my internship project. My name is Kaustubh Sahu, and I completed this project as part of my Data Analytics internship at Labmentix. Today I'll be walking you through a Power BI project I built around British Airways customer reviews.

[Slide 2 — Project Overview]

Let me start with some context. British Airways is a major full-service international airline, and like most airlines, it receives a steady stream of passenger reviews after every flight. These reviews matter because they capture something operational data can't — the actual, lived experience of a customer: how comfortable the seat was, how attentive the cabin crew were, whether the food was decent, and ultimately, whether they'd recommend the airline to someone else. For this project, I took a dataset of 1,324 individual passenger reviews and turned it into a structured, interactive Power BI report — something a customer experience or operations team could actually use to make decisions, rather than scrolling through raw review text one at a time.

[Slide 3 — Business Objectives]

That leads into the business problem this project addresses. Airline reviews typically arrive as a mix of free text and star-style ratings, scattered across different touchpoints, with no single consolidated view. That makes it genuinely hard to answer simple but important questions — like which service area is dragging down satisfaction, or whether certain aircraft or routes are performing worse than others. So my objectives were to bring all of this into one clean data model, build a solid library of DAX measures on top of it, and then use that foundation to analyze satisfaction by service dimension, by aircraft and route, and by traveller segment — all inside one interactive, filterable report.

[Slide 4 — Dataset Overview]

Now, a quick look at the data itself. The core table contains 1,324 passenger reviews, covering 56 countries, over a hundred distinct aircraft labels, and more than 800 unique routes. Review dates run from March 2016 through October 2023. Every review includes descriptive fields like traveller type, seat class, and route, an overall rating on a one-to-ten scale, and six individual service ratings — seat comfort, cabin staff, food, ground service, entertainment, and value for money — each on a one-to-five scale. The data itself was sourced from two local Excel workbooks loaded through Power Query; there's no external database behind this, just well-structured spreadsheet data.

[Slide 5 — Data Preparation]

Before any of that data reached a dashboard, it went through a fair amount of preparation.

In Power Query, I promoted headers, corrected data types, and trimmed and cleaned every text field. I handled missing values — for instance, blank traveller-type entries were replaced with “Solo Leisure,” and placeholder ratings of negative one were converted to proper nulls. The Aircraft column needed the most attention: it had well over fifty inconsistent spellings — things like “B777,” “Dreamliner,” or “A320 Neo” — which I standardized into clean, consistent categories. I also built a separate table that unpivots the six service ratings into a long format, which made it possible to compare all service dimensions side by side in a single chart. On the modeling side, I’ll be upfront that the file shows exactly one defined relationship — reviews linked to a country reference table — and I want to be transparent about that rather than assume a more complex model than what’s actually there.

[Slide 6 — Dashboard 1: Executive Overview]

With that foundation in place, let’s walk through the three dashboards. The first page, the Executive Overview, acts as a landing page — it shows total reviews, average rating, recommendation rate, seat comfort, and coverage across countries and aircraft, all up front. Below that sit a satisfaction map by country, a recommendation donut chart, a bar chart comparing recommendation rate by traveller type, and a trend line tracking average rating over time. The standout finding here is that only about 43 percent of reviewers said they’d recommend British Airways, and the overall rating distribution is fairly polarized — a large cluster of very low scores alongside a smaller group of high ones, rather than a normal, centered distribution.

[Slide 7 — Dashboard 2: Service Quality Analysis]

Now let’s move to the second dashboard, which drills into service quality specifically. This page breaks the experience down into its six components — comfort, staff, food, ground service, entertainment, and value — and lets you slice each one by traveller type and seat class. Cabin staff come out as the strongest-performing area, while food quality is consistently the weakest across almost every seat class. Another important observation from this page: Business Class travellers actually report lower overall ratings than Economy or First Class passengers, despite paying a premium — which is a meaningful signal worth investigating further.

[Slide 8 — Dashboard 3: Aircraft & Customer Insights]

The third and final dashboard shifts focus to aircraft, routes, and review credibility. It shows which aircraft types receive the most reviews — the A320 leads by a wide margin — along with rating patterns by route. It also splits reviews by verification status, and based on these findings, verified reviews, which make up roughly 92 percent of the dataset, report noticeably higher satisfaction than unverified ones. That’s a useful context to keep in mind whenever interpreting the headline numbers.

[Slide 9 — Business Recommendations]

Based on these findings across all three dashboards, a few clear recommendations emerge. First, food and beverage quality should be the top priority for improvement, since it’s the lowest-scoring area almost everywhere. Second, the Business Class experience deserves closer scrutiny given it underperforms Economy and First Class. Third, aircraft- and route-level ratings can guide where to focus maintenance or service investment. Fourth, growing the share of verified reviews would both improve satisfaction signals and strengthen the

reliability of future analysis. And finally, the recommendation-rate trend line is worth monitoring continuously, since it's an early indicator of shifting customer sentiment, with particular attention to Family Leisure travellers, who currently report the lowest average satisfaction of any segment.

[Slide 10 — Project Learnings]

Working on this project let me apply the full analytics workflow end to end — Power Query for data preparation, DAX for building a reusable measures layer, relational data modeling, and dashboard design grounded in business storytelling rather than just charts for their own sake.

[Slide 11 — Conclusion]

To bring it all together — this project converted 1,324 raw passenger reviews into a clean, three-dashboard Power BI report backed by a proper data model and fourteen DAX measures. It highlights genuine strengths, like cabin staff service, alongside clear opportunities, particularly food quality and the Business Class experience. More broadly, it shows how a business can move from scattered customer feedback to a single, evidence-based view that supports faster, better-informed decisions.

[Slide 12 — Thank You]

Thank you very much for your time — I'm happy to answer any questions about the data, the modeling decisions, or the insights.

Approximate word count: ~1,020 words — at a natural speaking pace of roughly 130-140 words per minute, this delivers in about 7.5 minutes.
